Suppose that a quantum circuit with K elementary gates is known for a unitary matrix U , and assume that U^m is a scalar matrix for some positive integer m . We show that a function of U can be realized on a quantum computer with at most $O(mK + m^2 \log m)$ elementary gates. The functions of U are realized by a generic quantum circuit, which has a particularly simple structure. Among other results, we obtain efficient circuits for the fractional Fourier transform.

PACS numbers: 03.67.Lx

Let U be a unitary matrix, $U \in \mathcal{U}(2^n)$. Suppose that a fast quantum algorithm is known for U , which is given by a factorization of the form

$$U = U_1 U_2 \cdots U_K, \quad (1)$$

where the unitary matrices U_i are realized by controlled-not gates or by single qubit gates [1]. We are interested in the following question:

Are there efficient quantum algorithms for unitary matrices, which are functions of U ?

The question is puzzling, because the knowledge of the factorization (1) of U does not seem to be of much help in finding similar factorizations for, say, $V = U^{1/3}$. The purpose of this letter is to give an answer to the above question for a wide range of unitary matrices U .

Our solution to this problem is based on a generic circuit which implements arbitrary functions of U , assuming that U^m is a scalar matrix for some positive integer m . If m is small, then our method provides an efficient quantum circuit for V .

Notations. We denote by $\mathcal{U}(m)$ the group of unitary $m \times m$ matrices, by $\mathbf{1}$ the identity matrix, and by $\mathbb{C}$ the field of complex numbers.

I. PRELIMINARIES

We recall some standard material on matrix functions, see [2, 3, 4] for more details. Let U be a unitary matrix. The spectral theorem states that U is unitarily equivalent to a diagonal matrix D , that is, $U = TDT^\dagger$ for some unitary matrix T . The elements λ_i on the diagonal of $D = \text{diag}(\lambda_1, \dots, \lambda_{2^n})$ are the eigenvalues of U .

Let f be any function of complex scalars such that its domain contains the eigenvalues λ_i , $1 \leq i \leq 2^n$. The matrix function $f(U)$ is then defined by

$$f(U) = T \text{diag}(f(\lambda_1), \dots, f(\lambda_{2^n})) T^\dagger,$$

where T denotes the diagonalizing matrix of U , as above.

Notice that any two scalar functions f and g , which take the same values on the spectrum of U , yield the same matrix value $f(U) = g(U)$. In particular, one can find an interpolation polynomial g , which takes the same values as f on the eigenvalues λ_i . It is possible to assume that the degree of g is smaller than the degree of the minimal polynomial of U . In other words, $V = f(U)$ can be expressed by a linear combination of integral powers of the matrix U ,

$$V = f(U) = \sum_{i=0}^{m-1} \alpha_i U^i, \quad (2)$$

where m is the degree of the minimal polynomial of the matrix U , and $\alpha_i \in \mathbb{C}$ for $i = 0, \dots, m-1$. In order for V to be unitary, it is necessary and sufficient that the function f maps the eigenvalues λ_i of U to elements on the unit circle.

Remark. There exist several different definitions for matrix functions. The relationship between these definitions is discussed in detail in [5]. We have chosen the most general definition that allows to express the function values by polynomials.

II. THE GENERIC CIRCUIT

Let U be a unitary $2^n \times 2^n$ matrix with minimal polynomial of degree m . We assume that an efficient quantum circuit is known for U . How can we go about implementing the linear combination (2)? We will use an ancillary system of μ quantum bits, where μ is chosen such that $2^{\mu-1} < m \leq 2^\mu$ holds. This will allow us to create the linear combination by manipulating somewhat larger matrices, which on input $|0\rangle \otimes |\psi\rangle \in \mathbb{C}^{2^\mu} \otimes \mathbb{C}^{2^n}$ produce the state $|0\rangle \otimes V|\psi\rangle$.

FIG. 1: A quantum circuit realizing the block diagonal matrix $A = \text{diag}(1, U, U^2, \dots, U^{2^{\mu-1}})$.

We first bring the ancillary system into a superposition of the first m computational base states, such that an input state $|0\rangle \otimes |\psi\rangle \in \mathbb{C}^{2^\mu} \otimes \mathbb{C}^{2^n}$ is mapped to the state

$$\frac{1}{\sqrt{m}} \sum_{i=0}^{m-1} |i\rangle \otimes |\psi\rangle. \quad (3)$$

This can be done by acting with a $2^\mu \times 2^\mu$ unitary matrix B on the ancillary system, where the first column of B is of the form $1/\sqrt{m}(1, \dots, 1, 0, \dots, 0)^t$. Efficient implementations of B exist.

Notice that there exists an efficient implementation of the block diagonal matrix $A = \text{diag}(1, U, U^2, \dots, U^{2^\mu-1})$. Indeed, A can be composed of the matrices U^{2^η} , $0 \leq \eta < \mu$, conditioned on the μ ancillae bits. The resulting implementation is shown in Fig. 1. The state (3) is transformed by this circuit into the state

$$\frac{1}{\sqrt{m}} \sum_{i=0}^{m-1} |i\rangle \otimes U^i |\psi\rangle. \quad (4)$$

In the next step, we let a $2^\mu \times 2^\mu$ matrix M act on the ancillae bits. We choose M such that the state (4) is mapped to

$$\frac{1}{\sqrt{m}} \sum_{k=0}^{m-1} |k\rangle \otimes U^k V |\psi\rangle \quad (5)$$

It turns out that M can be realized by a unitary matrix, assuming that the minimal polynomial of U is of the form $x^m - \tau$, $\tau \in \mathbb{C}$. This will be explained in some detail in the next section.

We apply the inverse $A^\dagger$ of the block diagonal matrix A . This transforms the state (5) to

$$\frac{1}{\sqrt{m}} \sum_{k=0}^{m-1} |k\rangle \otimes V |\psi\rangle. \quad (6)$$

We can clean up the ancillae bits by applying the $2^\mu \times 2^\mu$ matrix $B^\dagger$. This yields then the output state

$$|0\rangle \otimes V |\psi\rangle = |0\rangle \otimes f(U) |\psi\rangle. \quad (7)$$

The steps from the input state $|0\rangle \otimes |\psi\rangle$ to the final output state $|0\rangle \otimes V |\psi\rangle$ are illustrated in Fig. 2 for the case $\mu = 2$.

FIG. 2: Generic circuit realizing a linear combination V . The case $\mu = 2$ is shown.

The following theorem gives an upper bound on the complexity of the method. We use the number of elementary gates (that is, the number of single qubit gates and controlled-not gates) as a measure of complexity.

Theorem 1 *Let U be a $2^n \times 2^n$ unitary matrix with minimal polynomial $x^m - \tau$, $\tau \in \mathbb{C}$. Suppose that there exists a quantum algorithm for U using K elementary gates. Then a unitary matrix $V = f(U)$ can be realized with at most $O(mK + m^2 \log m)$ elementary operations.*

Proof. A matrix acting on $\mu \in O(\log m)$ qubits can be realized with at most $O(m^2 \log m)$ elementary operations, cf. [1]. Therefore, the matrices $B, B^\dagger$, and M can be realized with a total of at most $O(3m^2 \log m)$ operations.

If K operations are needed to implement U , then at most $14K$ operations are needed to implement $\Lambda_1(U)$, the operation U controlled by a single qubit. The reason is that a doubly controlled NOT gate can be implemented with 14 elementary gates [6], and a controlled single qubit gate can be implemented with six or fewer elementary gates [1].

We observe that $2^\mu - 1$ copies of $\Lambda_1(U)$ suffice to implement A . Indeed, we certainly can implement $\Lambda_1(U^{2^k})$ by a sequence of 2^k circuits $\Lambda_1(U)$. This bold implementation yields the estimate for A . Typically, we will be able to find much more efficient implementations. Anyway, we can conclude that A and $A^\dagger$ can both be implemented by at most $14(2^\mu - 1)K \in O(14mK)$ operations. Combining our counts yields the result. $\square$

III. UNITARITY OF THE MATRIX M

It remains to show that the state (4) can be transformed into the state (5) by acting with a unitary matrix M on the system of μ ancillae qubits. This is the crucial step in the previously described method.

Let U be a unitary matrix with a minimal polynomial of degree m . A unitary matrix $V = f(U)$ can then be represented by a linear combination

$$V = \sum_{i=0}^{m-1} \alpha_i U^i. \quad (8)$$

We will motivate the construction of the matrix M by examining in some detail the resulting linear combinations of the matrices $U^k V$. From (8), we obtain

$$U^k V = \sum_{i=0}^{m-1} \alpha_i U^{i+k}. \quad (9)$$

Suppose that the minimal polynomial of U is of the form $m(x) = x^m - g(x)$, with $g(x) = \sum_{i=0}^{m-1} g_i x^i$. The right hand side of (9) can be reduced to a polynomial in U of degree less than m using the relation $U^m = g(U)$:

$$U^k V = \sum_{i=0}^{m-1} \beta_{ki} U^i.$$

The coefficients β_{ki} are explicitly given by

$$(\beta_{k0}, \beta_{k1}, \dots, \beta_{k(m-1)}) = (\alpha_0, \alpha_1, \dots, \alpha_{m-1}) P^k$$

where P denotes the companion matrix of $m(x)$, that is,

$$P = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ g_0 & g_1 & g_2 & \cdots & g_{m-1} \end{pmatrix}.$$

The $2^\mu \times 2^\mu$ matrix M is defined by

$$M = \begin{pmatrix} C & 0 \\ 0 & \mathbf{1} \end{pmatrix},$$

where $C = (\beta_{ki})_{k,i=0,\dots,m-1}$, and $\mathbf{1}$ is a $(2^\mu - m) \times (2^\mu - m)$ identity matrix. Under the assumptions of Theorem 1, it turns out that the matrix M is unitary. Before proving this claim, let us formally check that the matrix M transforms the state (4) into the state (5). If we apply the matrix M to the ancillary system, then we obtain from (4) the state

$$\begin{aligned} \frac{1}{\sqrt{m}} \sum_{i=0}^{m-1} M |i\rangle \otimes U^i |\psi\rangle &= \frac{1}{\sqrt{m}} \sum_{k,i=0}^{m-1} \beta_{ki} |k\rangle \otimes U^i |\psi\rangle \\ &= \frac{1}{\sqrt{m}} \sum_{k=0}^{m-1} |k\rangle \otimes \sum_{i=0}^{m-1} \beta_{ki} U^i |\psi\rangle \\ &= \frac{1}{\sqrt{m}} \sum_{k=0}^{m-1} |k\rangle \otimes U^k V |\psi\rangle \end{aligned}$$

which coincides with (5), as claimed.

Lemma 2 *Let U be a unitary matrix with minimal polynomial $m(x) = x^m - \tau$. Let V be a matrix satisfying (2). If V is unitary, then M is unitary.*

Proof. It suffices to show that the matrix C is unitary. Notice that the assumption on the minimal polynomial $m(x)$ implies that C is of the form

$$C = \begin{pmatrix} \alpha_0 & \alpha_1 & \cdots & \alpha_{m-2} & \alpha_{m-1} \\ \tau\alpha_{m-1} & \alpha_0 & \cdots & \alpha_{m-3} & \alpha_{m-2} \\ \vdots & \vdots & & \ddots & \vdots \\ \tau\alpha_1 & \tau\alpha_2 & \cdots & \tau\alpha_{m-1} & \alpha_0 \end{pmatrix},$$

that is, C is obtained from a circulant matrix by multiplying every entry below the diagonal by τ . In other words, we have

$$C = \left([\tau]_{i>j} \alpha_{j-i \bmod m} \right)_{i,j=0,\dots,m-1}$$

where $[\tau]_{i>j} = \tau$ if $i > j$, and $[\tau]_{i>j} = 1$ otherwise.

Note that the inner product of row a with row b of matrix C is the same as the inner product of row $a+1$ with row $b+1$. Thus, to prove the unitarity of C , it suffices to show that

$$\delta_{a,0} \stackrel{!}{=} \langle \text{row } a | \text{row } 0 \rangle = \sum_{j=0}^{a-1} \tau \overline{\alpha_{j-a}} \alpha_j + \sum_{j=a}^{m-1} \overline{\alpha_{j-a}} \alpha_j \quad (10)$$

holds, where $\delta_{a,0}$ denotes the Kronecker delta and the indices of α are understood modulo m .

Consider the equation

$$\mathbf{1} = V^\dagger V = \left(\sum_{i=0}^{m-1} \overline{\alpha_i} U^{-i} \right) \left(\sum_{i=0}^{m-1} \alpha_i U^i \right) \quad (11)$$

The right hand side can be simplified to a polynomial in U of degree less than m using the identity $\tau U^m = \mathbf{1}$. The coefficient of U^a in (11) is exactly the right hand side of equation (10). Since the minimal polynomial of U is of degree m , it follows that the matrices $U^0, U^1, \dots, U^{m-1}$ are linearly independent. Thus, comparing coefficients on both sides of equation (11) shows (10). Hence the rows of C are pairwise orthogonal and of unit norm. $\square$

A Simple Example. Let F_n be the discrete Fourier transform matrix

$$F_n = 2^{-n/2} (\exp(-2\pi i k \ell / 2^n))_{k,\ell=0,\dots,2^n-1},$$

with $i^2 = -1$. Recall that the Cooley-Tukey decomposition yields a fast quantum algorithm, which implements F_n with $O(n^2)$ elementary operations. The minimal polynomial of F_n is $x^4 - 1$ if $n \geq 3$. Thus, any unitary matrix V , which is a function of F_n , can be realized with $O(n^2)$ operations.

For instance, if $n \geq 3$, then the fractional power F_n^x , $x \in \mathbf{R}$, can be expressed by

$$F_n^x = \alpha_0(x) I + \alpha_1(x) F_n + \alpha_2(x) F_n^2 + \alpha_3(x) F_n^3,$$

where the coefficients $\alpha_i(x)$ are given by (cf. [7]):

$$\begin{aligned} \alpha_0(x) &= \frac{1}{2}(1 + e^{ix}) \cos x, & \alpha_1(x) &= \frac{1}{2}(1 - ie^{ix}) \sin x, \\ \alpha_2(x) &= \frac{1}{2}(-1 + e^{ix}) \cos x, & \alpha_3(x) &= \frac{1}{2}(-1 - ie^{ix}) \sin x. \end{aligned}$$

In this case, F_n^x is realized by the circuit in Fig. 2 with $U = F_n$ and $M = (\alpha_{j-i}(x))_{i,j=0,\dots,3}$. The circuit can be implemented with $O(n^2)$ operations.

IV. LIMITATIONS

The previous sections showed that a unitary matrix $f(U)$ can be realized by a linear combination of the powers U^i , $0 \leq i < m$, if the minimal polynomial $m(x)$ of U is of the form $x^m - \tau$, $\tau \in \mathbf{C}$. One might wonder whether the restriction to minimal polynomials of this form is really necessary. The next lemma explains why we had this limitation:

Lemma 3 *Let U be a unitary matrix with minimal polynomial $m(x) = x^m - g(x)$, $\deg g(x) < m$. If $g(x)$ is not a constant, then the matrix M is in general not unitary.*

Proof. Suppose that $g(x) = \sum_{i=0}^{m-1} g_i x^i$. We may choose for instance $V = U^m = g(U)$. Then the norm of first row in M is greater than 1. Indeed, we can calculate this norm to be $|g_0|^2 + |g_1|^2 + \dots + |g_{m-1}|^2$. However, $|g_0|^2 = 1$, because g_0 is a product of eigenvalues of U . By assumption, there is another nonzero coefficient g_i , which proves the result. $\square$

V. EXTENSIONS

We describe in this section one possibility to extend our approach to a larger class of unitary matrices U . We assumed so far that $f(U)$ is realized by a linear combination (2) of linearly independent matrices U^i . The exponents were restricted to the range $0 \leq i < m$, where m is degree of the minimal polynomial of U . We can circumvent the problem indicated in the previous section by allowing m to be larger than the degree of the minimal polynomial.

Theorem 4 *Let $U \in \mathcal{U}(2^n)$ be a unitary matrix such that U^m is a scalar matrix for some positive integer m . Suppose that there exists a quantum circuit which implements U with K elementary gates. Then a unitary matrix $V = f(U)$ can be realized with $O(mK + m^2 \log m)$ elementary operations.*

Proof. By assumption, $U^m = \tau \mathbf{1}$ for some $\tau \in \mathbf{C}$. This means that the minimal polynomial $m(x)$ of U divides the polynomial $x^m - \tau$, that is, $x^m - \tau = m(x)m_2(x)$ for some $m_2(x) \in \mathbf{C}[x]$.

We may assume without loss of generality that the function f is defined at all roots of $x^m - \tau$. Indeed, we can replace f by an interpolation polynomial g satisfying $f(U) = g(U)$ if this is necessary.

Choose any unitary matrix $A \in U(2^n)$ with minimal polynomial $m_2(x)$. The minimal polynomial of the block diagonal matrix $U_A = \text{diag}(U, A)$ is $x^m - \tau$, the least common multiple of the polynomials $m(x)$ and $m_2(x)$. Express $f(U_A)$ by powers of the block diagonal matrix U_A :

$$f(U_A) = \text{diag}(f(U), f(A)) = \sum_{i=0}^{m-1} \alpha_i \text{diag}(U^i, A^i). \quad (12)$$

The approach detailed in Section III yields a unitary matrix M to realize this linear combination. On the other hand, we obtain from (12) the relation

$$f(U) = \sum_{i=0}^{m-1} \alpha_i U^i$$

by ignoring the auxiliary matrices A^i , $0 \leq i < m$. It is clear that a circuit of the type shown in Fig. 2 with μ chosen such that $2^{\mu-1} < m \leq 2^\mu$ implements this linear combination of the matrices U^i , $0 \leq i < m$, provided we use the matrix M constructed above. $\square$

VI. CONCLUSIONS

Few methods are currently known that facilitate the engineering of quantum algorithms. Linear algebra allowed us to derive efficient quantum circuits for $f(U)$, given an efficient quantum circuit for U , as long as U^m is a scalar matrix for some small integer m . This method can be used in conjunction with the Fourier sampling techniques by Shor [8], the eigenvalue estimation technique by Kitaev [9], and the probability amplitude amplification method by Grover [10], to design more elaborate quantum algorithms.
